•	Heh Michael, I'm looking forward to reading that one. Can I get it on line?	
	I don't have a clue. I really have not looked for that, maybe we should do a search, I think it's called Australian Shooter.	
	A little search I found this http://www.ssaa.org.au/shooter/shooter.html	
	500N	
	Thanks! Man I am itching to get back down under and hammer buffalo! If I can't get enough quota in Zim or Mozambique next year I am coming back to shoot w Paul. Had an offer of 1 buff and 2 cows, a tuskless in Zim, turned it down, told my man I would not even get on the plane for that little shooting. I am totally spo now getting to do the herd reduction with Paul! Hell I could shoot 50 buffalo there for what they wanted for those measly 3 and a little tuskless. I am building a MDM and a 458 Lott for Paul, he is going to hammer some buff with those.	oiled

	Michael Like you, I suffer from the same thing, having culled a few.	
	The biggest and the best is not always the mostest !!!! LOL	
	Nothing like wading into a herd of anything with a rifle, especially a bigger bore (375+), it really keeps you on your toes.	
	It's all the hard work afterwards cutting them up and packaging the meat	
	that kills you in 35+ degree heat but them's the breaks.	
	And with Paul, I reckon he would be good value out bush, always like talking to him.

(A)	Yes my man, nothing like getting into a small herd and hammer down. Best shoot I have ever been on, big fun.	
-#e	I consider Paul Truccolo a fine mate! I look very much forward to getting back there. He was home for a couple of days and headed back out tomorrow. Hell, it m be tomorrow there, or is it today, or yesterday? Aussie time keeps me confused! HEH	night

	Michael,	· ·
	Thanks for posting the photos. The Barnes bullets look good but I do like a BIG FLAT NOSE on a bullet. So what if it limits the penetration by 10 inche should be a hammer.	s or so. It really
	Corbin had a good idea of making the first band wider to prevent skidding as I have seen on most of the banded bullets like Northfork and GSC. I wil more and will probably make you them in .500 so we can ramp them up to higher velocity. My plans are to do like you said and go with 60% to 85% i	ll make a few in maybe 5%
	steps. Go ahaed and get some AC put in your range. I can't believe you don't already have that. I've been suffering in the heat too as my packing facility is degrees and then to go out in the fields at 100+ degrees is awful.	kept at 60
	I should be able to break away pretty soon to do some testing I hope.

	You are correct, larger meplat, some less penetration, but still MORE than enough for the mission of the solids. Hit's extremely hard, yes a big hamme	er.
	Ok, for the meplat size test, .500 is perfect. Weight wise something between 450 and 500 as a base weight is fine. We can test in the 50 B&M, and v of older 1:18 twists that can be tested too in the 50. The rest in 1:12.	we have a couple
	5% increments is perfect, even better, but I did not want to put too much on you, working with that bastard file of yours can be tough I know! That's they let me have and man I can destroy some things with that. If you drop a few to a 55% and 50% meplat that would be good too, no need really t	
	point.	
	I have a good window unit AC built in at the 50 yd bench, but it is not big enough to cool much past that little area up front. Maybe something at 25 I look into that.	too? Need to

Now the 320 is not a fluke either, Corbin, Sam and myself have tested the 320 several times now and at different times. So it is consistent.

I do not have a proper answer for why the 286 wants to veer off course, and the 320 does not. When looking at the nose, both appear to be the same to me. The answer to this question is above my pay grade, but the answer I know is not SD.

SD can only come into play if all things are equal with the exception of SD. Nose profile must be equal, construction, velocity, meplat. The problem we have here is that the 286 veers off course and is not stable during terminals, while the 320 is. Stabilization issue, not SD.

Ser and a second	These are helpful comparisons and tests. Once the penetration is straight, it seems that sectional density seems only part of the penetration prediction. Calibre size/or/overall weight seems to help.	
	Notice the following:	
	.338 250 gr BS were straight penetrating. SD is .313 The 2020fps impact was only 48".	
	The 2520fps impact was 60". (This last bullet will be pretty close to our 338 backup bullets this September, so I have a personal stake in these tests.)	
	However, the .458 450 grain has a .306 SD, less than the 338, but at an impact velocity of only 1950 fps (calculated from Michael's picture data) yet it still penetrated 57". Then the 500 grainers with a SD of .331 were able to penetrate 66" with impact velocities of around 2140.	
	Especially note the slow 338. Its impact velocity 2020 was faster than the .458 450 (1950 fps) and the 338 SD of .313 is better than the 458 SD of .306. Yet penetration was "only" 48" compared to 57" by the 458. Now both of those should give comfortable margins of penetration for anything on the planet, except rearend pachyderm and 1 wouldn't even be sure to recover them in a rearend buffalo shot.	
	The point is that the 338 needed to be driven to considerably faster speeds in order to match the penetration of the .458 450 grain solid. Since the 338 had a greater SD, it shouldn't have needed the extra 400-500 fps to overtake the 458. But apparently there is a penetration efficiency factor tha increases for a SD as its overall calibre and weight increase. It's not a huge factor, maybe in the vacinity of 20% penetration increase per percent of increased weight. Increase the bullet weight an extra 80% while the meplat and SD remain the same and one can expect a penetration increase in the 15-20% realm.	
	Hope that makes sense. It obviously would need quite a bit of testing before its 'factor percentage' would be known.

	I follow these posts with interest, but a few nagging considerations keep me wondering	
	You test a bullet at several varying velocities in a fairly uniform medium (but certainly not scientifically uniform) and some bullets penetrate much better than ot given. Varying the mepilat, shoulder form etc all seem to be factors in performance (that being defined as straight penetation, I think). I assume you do not adj twist rate to insure that impact velocity is the only variable you are tweaking? Do you care?	
	So, how are you guys assessing the change in rotational velocity (I know this is a moot concern to some in terms of stabilization-that's not my point, kind of). It accuracy testing, some loads seem to "settle down" much better/sooner than others and this settling down (perhaps a function of spin rate, CG/CB and constr uniformity-all affecting the bullets capability to track nose first (low(er/est) angle of repose) generally equals better accuracy.	
	Have you guys consdiered this in your experiments?	
	Hatcher indicates that an M2 ball round penetrates about (I forget the actual numbers, but they are significantly different) 18" at 100 yards, but 33" at 300 of hardwood, and attributes this to bullet stability (lower angle of repose/yaw).	
	As to construction- I completley agree that a pointy FMJ bullet (rearward CG will always tend to yaw rapidly upon pentration into a target medium and often (b design) break apart due to forces acting on the bullet as it is resisted by the medium. I assume a homogen-solid of similiar shape will simply yaw around and t base first until it runs out of momentum.	y ravel

	AC, Ignore Hatcher, Ackley, Whelen, etc. various studies WHEN they relate to military bullet ballistics data. We've had some fairly lively discussions within t regarding these issues but I'll try to resize them into a nutshell. The British military had a very difficult time designing a spire point FMJ bullet for the 303 ro reason??very simple, Geneva convention countries are required to utilize FMJ bullets when conducting war against each other. FMJ rounds punch nice li straight though a solders body with very little trauma unless a vital organ is hit. Therefore the workaround the convention agreement is to design a bullet stable in flightdon't recollect the distance but I believe it was in excess of 800yds while still impacting enhanced traum an a body by becoming unstable body mass. Brits had a hell of a time getting their new spire point bullet to become unstable within the body mass at close range while maintaining stable at extreme ranges. US had similar difficulties with is spire point 30-06 round. So while these studies are reading and do have their place for lo ballisticsit's just best to ignore them when your start discussing big bore cartridges and hunting bullet performance.	ound ttle holes that is within the bullet flight
	Now twist rate impact upon bullet within mass terminal performance. Yep we've had that discussion also…go back to page 18 and begin reading forward… regarding the performance of the .458 caliber 400gr Barnes Buster bullet. Bullet was used in two 45-70 lever action rifles…I believe the twist rates were 1 as well as the 458 B&M with…I think a 14" twist rate. There definitely was a difference in within mass terminal performance with the faster twist rate winn However as this thread was deemed as "unscientific" by some so this real world example was basically poo-pooed.	8" and 20"
	Biggest problem that big bores face is the lack of fast 10" twist rates unless the military has been involved in testing that caliber for long range sniper wor a specific popular cartridge's designer specified a fast twist rate for the cartridgeread here the 470 Capstick with its spec 10" twist rateotherwise you'l rate established at the turn of the 20th century during the beginnings of the C&C bullet days.	
	Myself, I've recently run into the issue of trying to get a barrel manufacturer to modify their "spec" barrel even when they note that for a slight extra charg they'll do it. I could get the spec 18.5" twist rate changed to a 10" twist rate but they refused to change their spec #10 contour barrel to a #6 contour bar when they offered the #6 contour barrel in calibers both smaller and larger than the caliber I was interested in…even then it would take a minumum of 6 r delivery for a barrel that didn't fully meet my needsso no joy there.	rreleven
	OK, I'll leave it at that.

$\langle \mathbf{A} \rangle$	Glad you are following with, and even more glad you are pitching in! Thanks!	
-fe	For solids, yes, performance is measured in straight line penetration, correct. Adjust twist rate? No, all the tests are done with real rifles and unless we ha built with a particular twist rate then we are sorta stuck with what we have. For instance, most 45/70s are at 1:18 to 1:20 or so, while most 458 Big Bore: 1:14. Yes, twist rate is a major factor when meplat size of the bullet is at 55% or so and cannot stabilize itself. So yes we care very much about twist rate factor.	s are at
	Rotational velocity, really not so sure that is much of a factor or not in what we are looking at, you are correct, as far as accuracy and Hatcher is correct as of better stability at the longer range. Of this I have no issue. I know you already know this, but just to point out we are testing "big bore" rifle bullets ( me 338s and 9.3s thrown in), anything related to studies of this sort really has little to do with our project, if anything. I do test close to some standards, reasons for this. First, I am on an indoor 50 yd range, benches at 25 and 50. It is pretty much a test facility as far as I am concerned, lot's of load data for carridges, bullet testing, 50 yd accuracy testing, things like that. I personally have not tested too much at longer ranges in many years, sight in at 50 has successful for me, and about the smallest bore rifle I have taken to the field in years has been a 416. A few times 10-12 yrs ago 338 and 358 calibers, mor rest have been 416 and up. The last time I had a small bore in the field was probably 2004 that being a 358 TA.	ostly-with a there are my various been very
	Now I probably use more solids than any shooter or hunter for sure in the field, I use them to back up everything nearly and it works great for me. Not jus use with 2cd shots on buff, first on elephant and hippo, but I use solids to back up on most other things such as plains game, bear and what have you. Bu primary use for solids is large, thick skinned game, buffalo, hippo, elephant. One does not shoot those animals at 300 yds. It is most of the time close, I kr started things off as little as 6 yds before, in one case with a bear it was 6 ft. But elephant are very much a lot of the time under 20 yds. Buffalo and hippo under 50. I did have to murder one buffalo at 90 yds once, it was awful, but he was a fine old bull and I could not help myself! The point being testing at c has more of an impact on what we do with big bore rifles and bullets, and has more validity than to even consider a 100 yds. If we have issues at close ra where we will have a problem. We want to sort those problems out long before going to the field, and that is exactly what we have been doing.	it our now I have mostly lose range
	As for a "pointy FMJ or Solid" yes, absolutely correct, it don't take long for it to turn ass to the front and become unstable. I tested some pointy 200 gr 338 long ago with exactly those results. I would have to look up that, but I have it. Thanks for the input, much appreciated! Stay with us and don't run off!	s not too

A.	How correct you are, getting a fast twist rate on some of our big bores is an issue. I was extremely lucky to get the 1:12 twist rate barrels for the .500s a A 1:12 can be had in 416 without a problem, all mine are 1:14. Wish I had known 5 yrs ago that twist rate was so important, now my 416 B&Ms have a te trying to stabilize 400 gr solids at 2300 fps or so. I have zero issues with 350-370 gr solids in them. All my 458 are 1:14, but not having any stability issu B&Ms at all at 1:14. I would rather have 1:10 or 1:12, but I don't. The new upcoming 410 B&M is stuck at 1:14, but the new 457 B&M and the Super Short going to be 1:10 from PacNor.	rrible time es with 458
	Of course we are all looking forward to RIP getting going with his very special 1:10 458 B&M and working with the marginal meplats of bullets like the Barr (perfect bullet for testing twists as we have already seen in both 458 and 500 caliber) It's marginal meplat size of 55-54% requires a fast twist to get bett performance. Had that meplat been 65% it could stabilize itself during terminals.	es Buster er
	As far as I am concerned we are dead spot on the twist rate issue, we have too much evidence backing that information. Twist is a major factor just behind nose profile/meplat size, which is NUMBER 1!

	Sam Spot on my friend! You will have to do the long range test work at 200 yds, I can't see that far! HEH.	
	Take a look back on all the 338 work we did on this thread and you will see that velocity and expansion has a lot to do with penetration. Almost in every case t slower velocity of the 338 Winchester penetrated deeper than the same bullets out of the 338 Ultra. With the exception of the great Barnes Banded solid, whic a little extra velocity! Made me wonder why I even bothered with a 338 Ultra?	he h likes

Dave Bush One of Us		Hide Post
	I did some bullet testing of my own this morning and I wanted to pass on the results. My testing is not as scientific as Michael's but I think it was pretty probati I was shooting from the bench at 50 meters. The media was two copy paper boxes filled with wet phone books. There was a total of 36-38 inches of phone boor The bullets tested were 400 grain. 458 Barnes Buster bullets and 250 grain 9.3 Barnes Banded Solid. Riles were a Marlin 45/70 guide gun with an 18.5 inch ba (1:20 twist) and a Blaser 9.3X62 with a 22.7 inch barrel (1:14 twist). I also shot a 250 grain 9.3 TSX and a 286 grain Woodleigh RN into the media as well wher done with the solids. Here is what I found out:	oks. rrel
	<ol> <li>Although I really, really wanted Michael to be wrong about the 9.3 banded solids, I got exactly the same results that he did. The first one into the box gave a 18 inches of straight line penetration but then it went down for about 8 inches and out of the second box. The second one went straight for about 18 inches th went up and right for about 6 inches and out of the second box. Neither bullet was recovered. Muzzle velocity was +/- 2500 fps. They just don't stay on course</li> </ol>	ien
	2. However, with respect to the 9.3, all the news was not bad. I also shot a 250 Barnes TSX into the same media and got 24 inches of straight penetration, a p perfect mushroom and I am guessing 100% weight retention. Muzzle velocity was -/+ 2500 fps. Excellent bullet! Finally, I shot a 286 grain Woodleigh RN into t media, got about 17 inches of penetration. The recovered bullet had three nice petals folded back to the crimping groove. Velocity was 2350-2400 fps. Good bu well.	the
	3. I also shot two Barnes Buster bullets into the box. Velocity in my little guide gun is about 1900 fps. Both went in the front and out the back. Penetration was straight for about 36-38 inches. Barnes says these bullets will shoot shoulder-to-shoulder on a bison. They are not kidding. <b>Excellent bullet</b>	
	As an aside, I pulled my Blaser 9.3X62 out of the case this morning, put it together and put on the scope. I fired one shot at the range to set the scope and the shooting from the bench, it was exactly where it was when I last took the scope off. If you are interested in a take down gun with a superb trigger that will sho it had eyes right out of the box, get a Blaser R93 now! P.S. I need to add a short post script here. I also shot some 300 Barnes TSX flat base bullets from my 45/70. They were running between 1900-2000 fps out of	oot like Fmy
	guide gun. One was shot at 50 meters. I found a piece of it and thought maybe my shot was badly placed so I moved up to about 20 meters and put another of the box. When I was cleaning up a chunk of it fell out on the ground. It had pretty much disintegrated. My advice would be to stay away from them. Dave	one in

Dave

Well your test is just fine, there are many who say mine aren't very scientific either, but results speak for themselves, and are repeatable whether I do it or you do, or Mike, or RIP or whomever. The p someones favorite bullet does not do well in the tests, then the tests must be flawed. This is bullet against bullet, but some have a hard time with that concept.

1. Sometimes I wish I was wrong, I have been very disappointed MANY times myself. Just when I thought I was getting close to getting it right, the tests said different, and it's back to the drawing boat 500 caliber solids I went through 6 generations of different bullets before getting there. And that can take a lot of time.

2. I am in 100% agreement with you, for what I want a 9.3 for the 250 Barnes TSX is my go to bullet! Not just Excellent----Extremely Excellent!

But I also must add this, I have found almost no bad 9.3 Bullets! I have been extremely pleased with nearly all the expanding 9.3s I have tested. Bullets that I would not use in lesser calibers, same b superb. I really like 9.3, even though I have never been to the field with it, I have high levels of confidence it will do what I ask of it.

3. I think the buster will be just dandy. It is not as good as the banded solids, because of the meplat size, but that is not it's intention either. A faster twist helps it tremendously. But for what it was d the job and give plenty of penetration. For all North American work it will be a great bullet. I have to do some accuracy tests with it, my 458 B&M did not like the only accuracy test I have done at 50 yd one go, I must do some more with it.

Tell me more about the 300 Barnes TSX? Was that the flat nose HP for the 45/70 lever guns? Or the pointy bullet? Actually I have had pretty good luck with both of those in the past. Will have to look of Back to the 9.3 solids. Sam is all over this. Yesterday between Corbin and I we got Sam busy on a few 9.3s to test. I asked for a 65-70% meplat of caliber size, and Sam came in dead on the money w has 3 to test, the short one on the left is 230 grs, the middle is 260 grs, and the long on the right is 318 grs. All with 68% meplat. Now what do you reckon will be the outcome of these?

06/26/2010 1

Also, I have a box of 9.3 286 North Fork solids on the way! I hope to have them next week, and be testing them next week for sure. Starting Monday I hope, we will be back on the North Fork CPS but

Now, if we can't find a proper 9.3 solid, if Barnes won't change the design, and the North Forks don't work either (I am sure they will with the meplat) damn if I won't get some made probably using on most likely. I am not going to be without a proper solid for any sort of work, even a 9.3 medium caliber. Oh, and Sam is not in the bullet making business either, just has the capability to make a few as Both he and I and Corbin would use that design if successful, and works not only good with penetration, but has to feed in my Winchesters, then we would take that to our bullet making guys for a sir clear that, don't wont anyone thinking Sam is competing with bullet business or anything, he is a shooter and very talented with his bastard file. In fact I am quite sure he has worn out his bastard file bullets, I will get him a new one when he visits next!

Michael

In the meantime Sam also made a couple of .500s that weigh in at 500 grs, another 9.3 in the middle, and on the end is a 6.5 that Corbin is stuck on! Nice work Sam!

12 C	Yes, while I have not messed with the 250s, I have a decent supply of the 300 flat nose HPs for the 45/70. I don't have info in front of me, but I am sure those some years ago and had really good results as I recall. I might look into that this week too, a little more extensively. One thing let's point out, and about.	
	enhancement in trauma transfer to animal tissue. And, penetration is deeper than any conventional expanding bullet. Penetration is never a bad thing 1 W Conventional if we loose our petals or shear, we get deeper penetration than if they hang on! I am a penetration freak, as we all know. Deeper penetrat we are touching and destroying tissue that otherwise would not be destroyed. This can't be bad. So before we consider that petals peeling is bad, let's le	tion means
	closer.	
	closer. Now when a conventional lead/jacket bullet starts to breakup we get the opposite effect, we get less penetration than if it holds the weight together or separate from the core. This is our conventional wisdom for a 100 yrs. And it's true, I will always consider a breakup of a conventional bullet a failure, eve time after time. Of course in some circumstances this is very desirable in missions in which penetration is not an issue, because intense trauma is inflicted Yes, this past week with just a little test work I looked like I had been in the pool afterwards.	does not n if it kills

	Posted 27 June 2010 23:21 Michael: Just one point about those Barnes 300 grain .458 TSX flat base bullets. Here is the problem as I see it. They are homogenous bullets with a very, very dee cavity so they are really long, even longer than a Speer .458 flat nose. With the limited capacity of the 45/70, I would rather shoot the Speer flat nose or m a 350 grain Hornady. You can drive them just as fast and the extra 100 grains of bullet is going to give you much better penetration on a big animal and w whether they will open up on a deer. Drive a .45 caliber bullet through a deer and he is yours. I just think the heavier bullets are a better choice. Dave DRSS	:p nose naybe even

	Dave Good point too. I have used the 350 Hornady since it hit the market way back. We know it's tough right up into 2400 fps that 458s can run it. Below 1600 l problems opening up, but who cares, like you said, it's already 458 caliber. I used to run the 350s at 1950 fps or so in the guide guns. S0 grs RL 7. Some g more, some a tad less. We tested the Speer the other week remember, it did very very good in the 458 B&M at 2200 fps. I was impressed with it.	juns a tad
	I will look into the Barnes again this week. I have a guide gun set up, load a few and see too. I would also like to test the 350 Speer in the 45/70 at that v I played with the pointy 300 458 and it did very good in the 458 B&M. But my favorite light bullet in the 458 B&M is the 350 TSX. It is excellent. M	velocity too.

	I want more than 40" on Water Buffalo - if I do a follow up ass end shot (i aim for and break the hip but want the bullet to penetrate as far as possible), one of the reasons I use heavy for calibre bullets like the 320gn Woodleigh in 9.3's.
